Tag av isen i Arktis kan føre til en skuddetrasjon i globalt land is refleksivitet

A new study suggests global warming could make snow darker and more frequent than previously forecast.

In the Arctic, the summer melt reduces ice to its minimum by September when the arrival of winter usually refreezes the sea ice.

In one model simulation, September sea ice coverage will shrink from about 2.8 million square miles (8 million square kilometers) to 718,000 square miles (2 million square kilometers) in a span of ten years.

Is en polarområde i eneste sin slags i Nord, med et høyt innhold av isrefleksivitet. Det vil si at den reflekterer mest av solstrålingen som treffer den.

En studie fra World Resources Institute viser at i løpet av de neste 100 år vil isdekningen i Arktis ha sunket med 2,8 millioner kvadratiske miles (8 millioner kvadratiske kilometer) til 718.000 kvadratiske miles (2 millioner kvadratiske kilometer) i løpet av ti år.
